Recognition of (r,ℓ) -partite Graphs

Abstract

The complexity to recognize if a graph has an (r, ℓ) -partition, i.e. if it can be partitioned into r cliques and ℓ independent sets, is well defined(1). However, as we will demonstrate, the literature-stabilished values for those on the P class can be improved. The following work provides a set of strategies and algorithms that pushes the previous results for the (2,1)-partite (from n^4 to n*m), (1,2)-partite (from n^4 to n*m) and (2,2)-partite (from n^{12} to n^2*m) recognition.

Keywords— (r, ℓ) -graphs, (r, ℓ) -partitions

1 Introduction

1.1 Current results

In this section we will explore the current state of the complexity analysis as r and ℓ grows. As we fullfill the following table we expose the strategies and how those can be used to enlight the more complex results.

The most trivial result is the recognition of the (1,0)-graphs, as in order to recognize it we just need to know if |E(G)| > 0. Therefore it's complexity is $\mathcal{O}(1)$.

1.1.1 m-bounded results

Naturally, we wish to find the complexity for those problems of small partition cardinality.

At (2), König showed that it takes $\mathcal{O}(m)$ steps to recognize a bipartite graph. For complete graphs, is enough to check if |E(G)| = n(n-1)/2, if it doesn't then we have an answer; If it does, checking vertex by vertex if it's neighborhood contains all other vertex is $\mathcal{O}(m)$.

For co-bipartite graphs recognition, we need only to verify if it's complement is a bipartite graph. The recognition of a split graph can be done using their vertex degrees (??), obtaining all vertices degrees is $\mathcal{O}(m)$ therefore the recognition of split graphs is $\mathcal{O}(m)$

1.1.2 *NP*-Complete results

A adequate strategy at this moment is to find when the recognition problem gets NPComplete.

At (3) is shown that 3-coloring a graph (i.e. assign a color between three possibles to each vertex such that no neighborhood repeats a color) is NP-Complete, it's trivial to

see how the 3-coloring of a graph can be reduced to the problem of finding if a graph is a (3,0)-graph, therefore the recognition of (3,0)-graphs is NP-Complete.

It's noticible that the recognition of (r, ℓ) -graphs is monotonic, and therefore if the recognition of (3, 0)-graphs are NP-Complete then the recognition of any (r, 0)-graph or $(3, \ell)$ -graph is NP-Complete for r > 3 and $\ell > 0$.

We can extrapolate these findings and argument that the recognition of a (0,3)-graph is also NP-Complete, as it is the same as recognize it's complement as a (3,0)-graph, and use the property of monotonicity to state that the recognition of any (r,3)-graph or $(0,\ell)$ -graph is NP-Complete for r>0 and $\ell>3$.

1.1.3 Frontier results

Finally, the frontier cases (1,2),(2,1) and (2,2) were subject of studies by Brandstädt(1,4). He's findings show that:

- Recognition of (1, 2)-graphs are $\mathcal{O}(n^4)$.
- Recognition of (2,1)-graphs are $\mathcal{O}(n^4)$.
- Recognition of (2,2)-graphs are $\mathcal{O}(n^{12})$.
